

Dylan Smith Leading II 2

1. The 6 dplyr for manipulating data frames are `select()`, `filter()`, `mutate()`, `rename()`, `recode()`, and `arrange()`.
2. `mutate()` can be used to transform or recode variables and `recode()` recodes variable values.
3. `pools2 <- select(pools, water_capacity, age)`
4. `Filter(leadership, gender == "F", (q2 == 5) | (q3 == 4))`
5. The `%>%` operator passes the result on the left-hand side to the first parameter of the function on the right-hand side. This is more efficient and easier to read.
6. We are initializing a new variable `high-potentials` which filters rows of `leadership` to only rows where `total_score > 10` then selects only `ID`, `country`, and `mean_score` then arranges by `country` and `mean_score`.
