

Dylan Smith Reading #3

1. `ggplot()` + `geom` generates a graph with the specified geometry. For example:
`ggplot()` + `geom-boxplot()` generates a boxplot
`ggplot()` + `geom-bar()` generates a bar chart
2. To superimpose groups of observations on a single graph use the `aes()` function to map to a specific color, shape, or line type.
3. `scale_y_continuous(limits = c(50, 100), breaks = seq(50, 100, by = 10))`
4. Use the `labs()` function to provide custom labels.
5. When `data =` and `mapping =` are placed inside `ggplot()` they become the default for any attached `geom()` functions. Versus when placed inside the `geom()` function they are only applied to that specific `geom()` function.
6. The `aes()` function is used to map variables to the visual characteristics of the graph.

```
7. ggplot(pools, aes(x=age, y=water_capacity, color=pool_shape,  
  shape=pool_shape)) + geom_point() +  
  scale_x_continuous(limits=c(0,20), breaks=seq(0,20,  
    by=2)) + scale_color_manual(values =  
    c(circle="maroon2", irregular="seagreen2", rectangle="purple1"))
```
